THE "WATERMASTER" IS RETIRING

The Watermaster: Commissioner watches over the Humboldt River

Flooding allows everyone to get the precious water they need

> By Forrest Newton The Humboldt Sun

WINNEMUCCA - All that water running down the Humboldt River is not available to just anybody that wants it and has not been since 1939, because it already belongs to somebody

"Basically there isn't any other water for appropriation," Humboldt Water Distribution District Water Commissioner Steve Del Soldato said.

From Battle Mountain to Ryc Patch Reservoir, he watches over the flow of water and does his best to make sure those who are allocated the water actually get it - if it is available.

"There's been years where some of these ranches don't get rrigated at all," he said.

Additionally, Del Soldato's area ranges from Quinn River to Paradise to Kingston Creek. The Pershing County Water Conservation District takes over at Rye Patch.

oversees the entire Humboldt a stream or river.

REGION WIDE ET ANALYSIS

DRI

Groundwater Discharge via Evapotranspiration

Justin Huntington, Research Professor, Hydrology

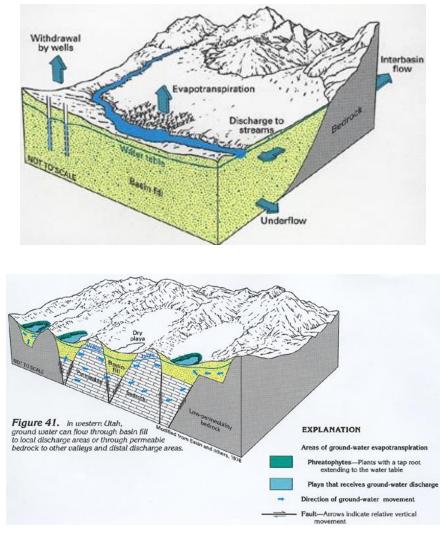

Paradise Valley, NV

Groundwater Discharge via Evapotranspiration

Objective

- Delineate areas where phreatophytes discharge groundwater through the process of evapotranspiration
- Use best available science to estimate the rates of groundwater evapotranspiration (ETg) from phreatophyte vegetation
- Summarize and compare to previous studies, and provide results to USGS and DRI groundwater modeling groups to use for calibration of groundwater models

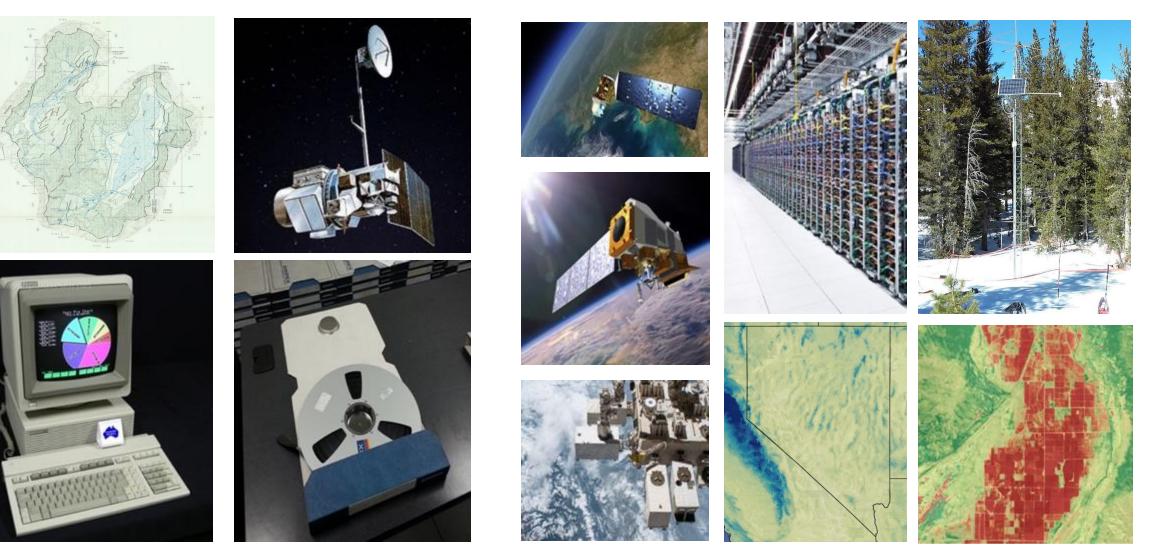

USGS HA730C – Groundwater Atlas of U.S.

Satellite and Climate Data

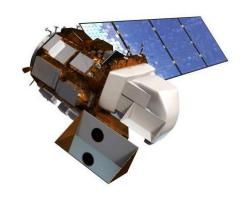

1960s-1980s

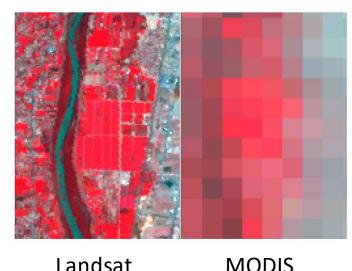

1980s-current

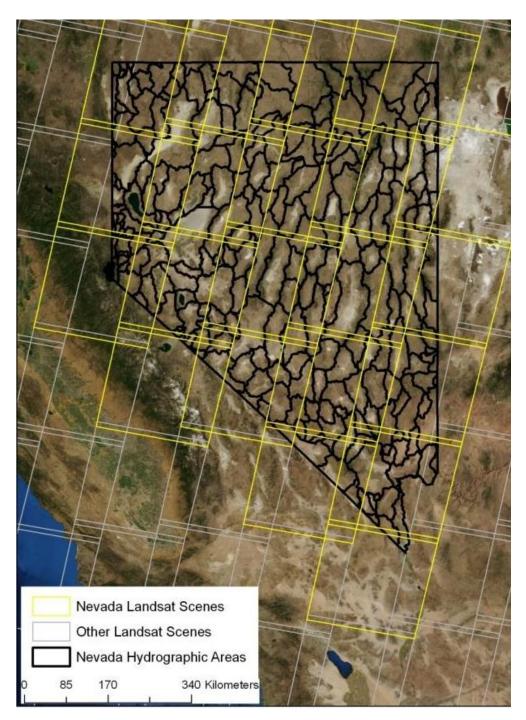

Geospatial Data Approach

- Previous phreatophyte boundaries, aerial imagery, Landsat imagery, digital elevation models, soils data, wells and water levels, field surveys of phreatophytes
- Landsat satellite imagery to compute vegetation indices
 - 1985-2015, summer period
- gridMET weather data for estimating precipitation and evaporative demand
 - Solar radiation, temperature, humidity, and wind speed

Groundwater Discharge from Phreatophyte Vegetation, Humboldt River Basin, Nevada

Project Description

Groundwater evapotranspiration (ETg) from phreatophyte vegetation is the primary component of natural groundwater discharge within the Humboldt River Basin. This report summarizes previous study estimates of ETg, and details methods and results of updated groundwater discharge areas, ETg rates, and ETg volume estimates developed in this study. Estimates derived in this study are summarized for the period of 1985.2015 and were based on a consistent placebased approach that relies on Geographic Information System and groundwater level data and a least-squares regression model that relates Landsat vegetation indices with evaporative demand, precipitation, and in-situ estimates of phreatophyte ET. Median annual ETg rates and volumes reported in this study are representative of pre-development conditions. Where irrigated areas were identified, ETg rates were adjusted to reflect the phreatophyte vegetation that likely occupied irrigated areas prior to cultivation. Results from this study were used to inform groundwater modeling studies by the U.S. Geological Survey and the Desert Research Institute, in cooperation with Nevada Division of Water Resources, to support conjunctive water management.

Results and datasets are summarized and documented in the form of maps, graphs, tables, geodatabases, and metadata following Federal Geographic Data Committee standards and are available at www.dri.edu/humboldt-etg. Estimated pre-development total annual ETg volumes for the upper, middle, and lower Humboldt River basin are 158,500, 361,600, 55,900 ac-ft/yr, and 85,700, 248,400, and 46,100 ac-ft/yr when riparian lands are excluded, respectively. Discharge areas and median annual ETg rates and volumes were compared to previous estimates for respective ET Units and Hydrographic Areas. Results reported for the upper Humboldt River Basin indicate that potential areas of groundwater discharge are generally lower, and ETg rates and Smith (2013). Results reported for the middle Humboldt River Basin indicate that ETg rotred is the middle Humboldt River and Smith (2013). Results reported for the middle Humboldt River sain indicate that ETg rotred so and Smith (2013). Results reported for the middle Humboldt River sain indicate so and Smith (2013). Results reported for the middle Humboldt River sain indicate that ETg volumes are higher in six, and lower in seven HAs when compared to previous estimates in the middle Humboldt River Basin are also generally less than one half when compared to those reported by Regrer (2000). Differences in ETg volumes are primarily due to differences in ETg rates and differences in groundwater discharge areas.

This study used place-based satellite remote sensing, climate and GIS datasets, groundwater levels, and in-situ based phreatophyte ET empirical regression models to estimate potential areas of groundwater discharge, and ETg rates and volumes within the Humboldt River Basin. Future study estimates of ETg within the Humboldt River Basin could be improved by refining delineation of groundwater discharge areas, variability in ETg with respect to climate and land use change, and collection of in-situ ET estimates in areas where large uncertainty exists.

Appendix D is the result of

1 computing the spatial average ETg rate for each ET Unit for each year as a table of values

2 reading the table of spatial average ETg rates for each year, and computing the temporal median for each ET Unit

3 multiplying the temporal median ETg rate by respective ET Unit areas to produce volumes

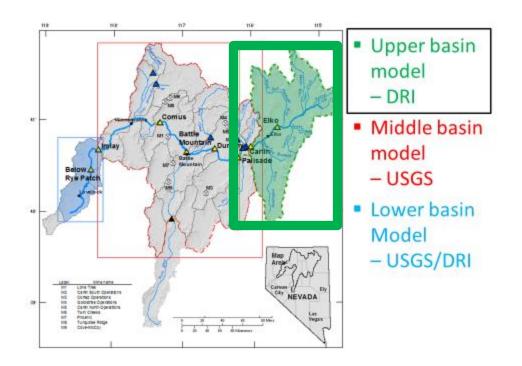

4 summing the median ETg volumes across all ET Units, and all ET Units less riparian.

Summary

- The purpose of this study was to develop and summarize new groundwater discharge areas, ETg rates, and ETg volumes within the Humboldt River Basin using best available science.
- The approaches applied in this study to estimate ETg were based on state-of-the-art satellite remote sensing, climate modeling, GIS datasets, groundwater levels, and in-situ ET estimates from phreatophyte vegetation in the Great Basin
 - Delineated and revised potential areas of groundwater discharge
 - Estimated ETg rates from phreatophyte vegetation using a measurement-based regression model
- Summarize ETg rates and volumes by land cover type (e.g. phreatophyte, riparian, meadow) and compared to previous studies
- Provided results to USGS and DRI groundwater modeling teams for integration into models
- Produced a technical report and GIS data that are publicly available -<u>https://www.dri.edu/humboldt-etg</u>

USGS Seepage Sites
 USGS Stream Gauge

0 5 10 20 Miles

A. Gaining stream

Stream with streambed and streambank sediments less permeable than surrounding aquifer sediments.

Simulating Rivers

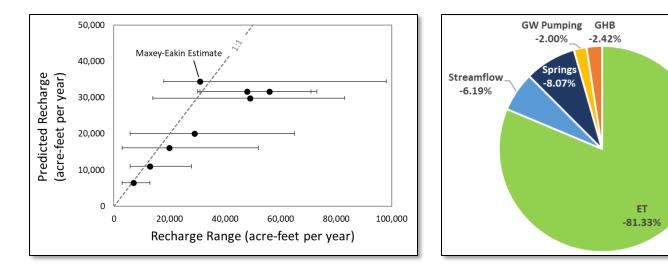

- MODFLOW RIV package
- Allows gaining and losing based on water table elevation.
- Does not allow for ephemeral conditions.
- Riverbed conductance calibrated to match observed streamflow
- Riverbed conductance is important to estimated stream capture.

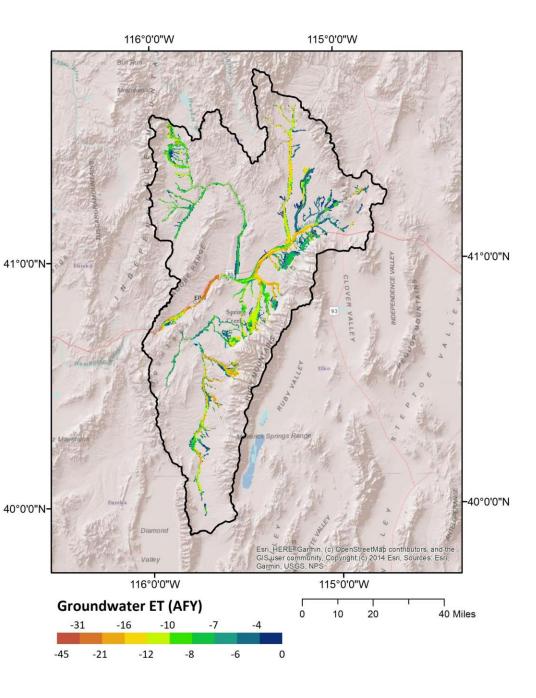

Pre-GW Development Water Budget

Inflows: Recharge adjusted at hydrographic basin scale to match estimated outflows.

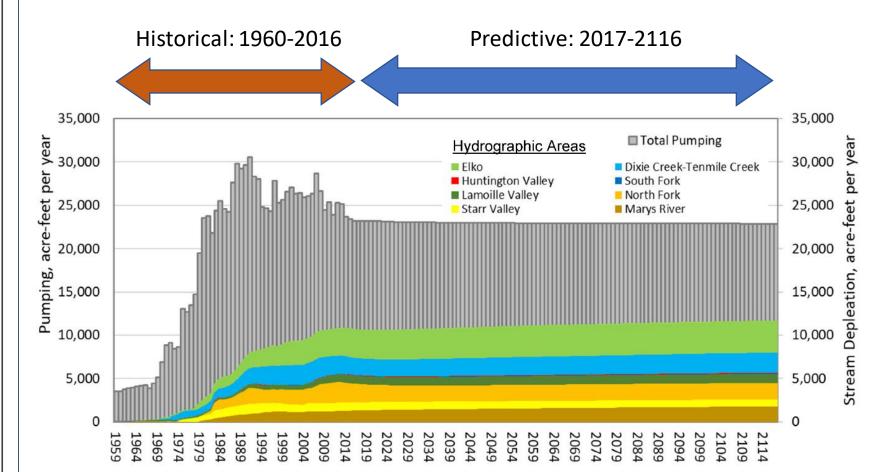

- Previous Studies: 147,300-470,000 AFY
- Updated Maxey-Eakin: 253,000 AFY
- Simulated Total=177,443 AFY

<u>Outflows</u>: Streamflow, springs, interbasin gw flow and phreatophyte Evapotranspiration (ET)

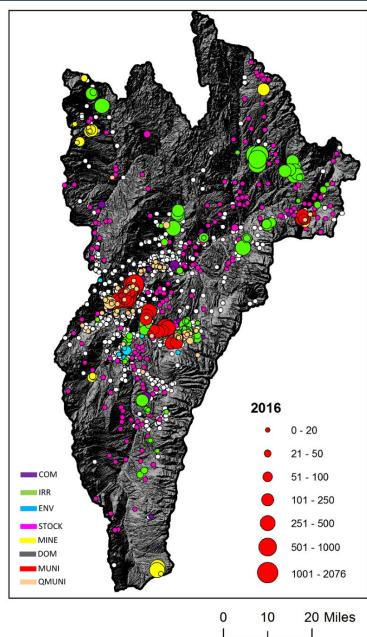

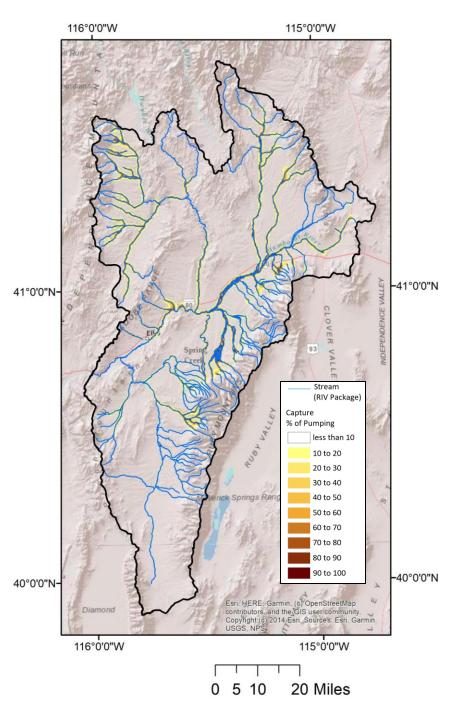

The amount of pumping in each basin explains a significant component of stream capture (r²=0.65). The remaining variability is due to proximity to stream, subsurface hydraulic properties, riverbed permeability (conductance).

River Capture Maps

Year 1

• River capture to satisfy hypothetical pumping is very low & limited to locations immediately adjacent to a river.

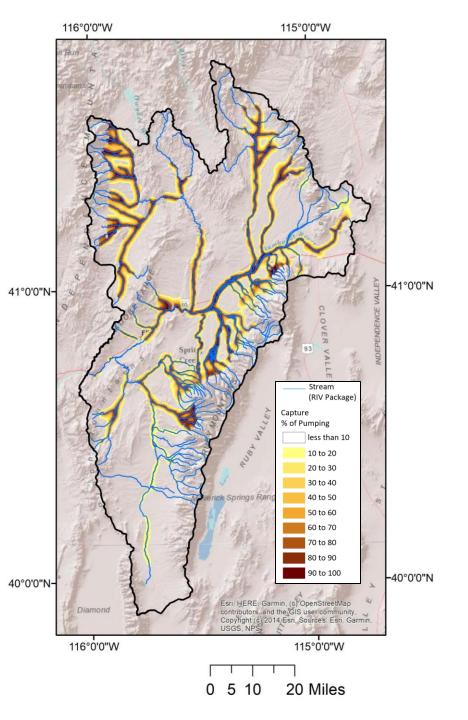

River Capture Maps

Year 1

• River capture to satisfy hypothetical pumping is very low & limited to locations immediately adjacent to a river.

Year 10

• Capture increases, expands away from the river and spatial variability along river reaches emerges.

River Capture Maps

Year 1

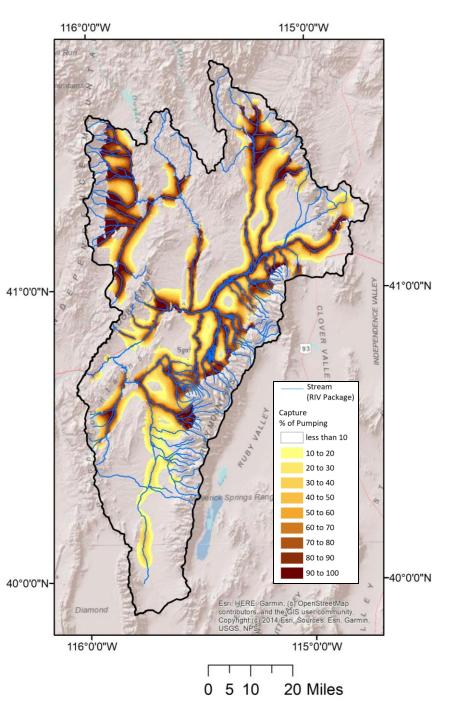

• River capture to satisfy hypothetical pumping is very low & limited to locations immediately adjacent to a river.

Year 10

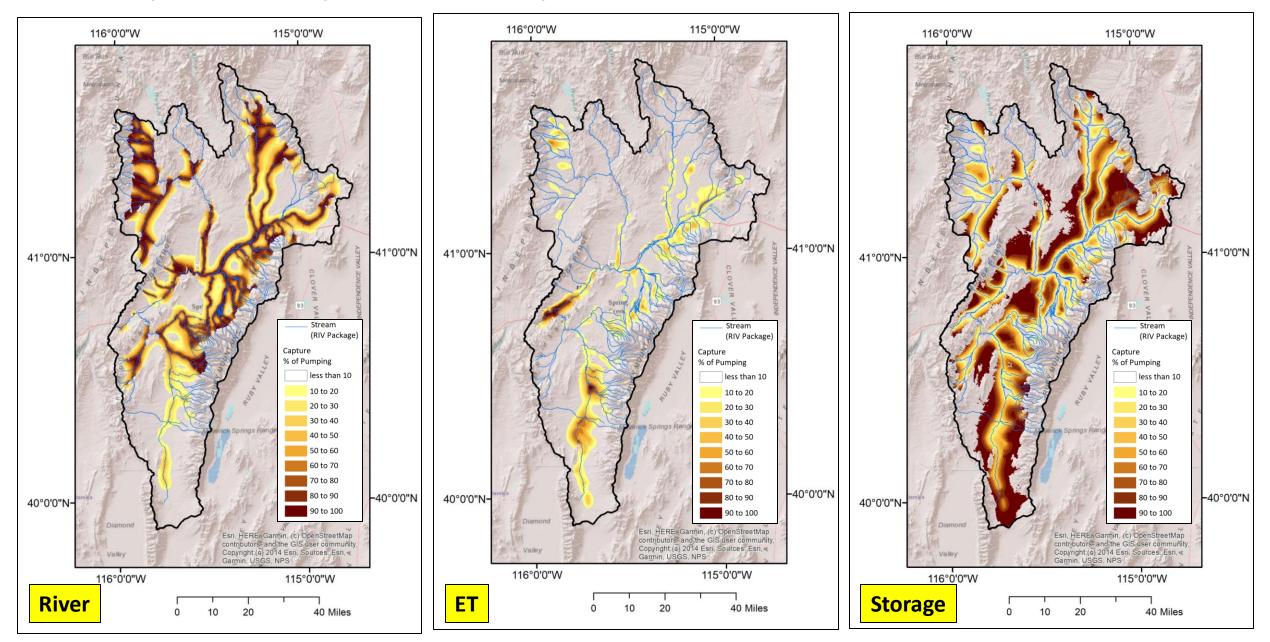

• Capture increases, expands away from the river and spatial variability along river reaches emerges.

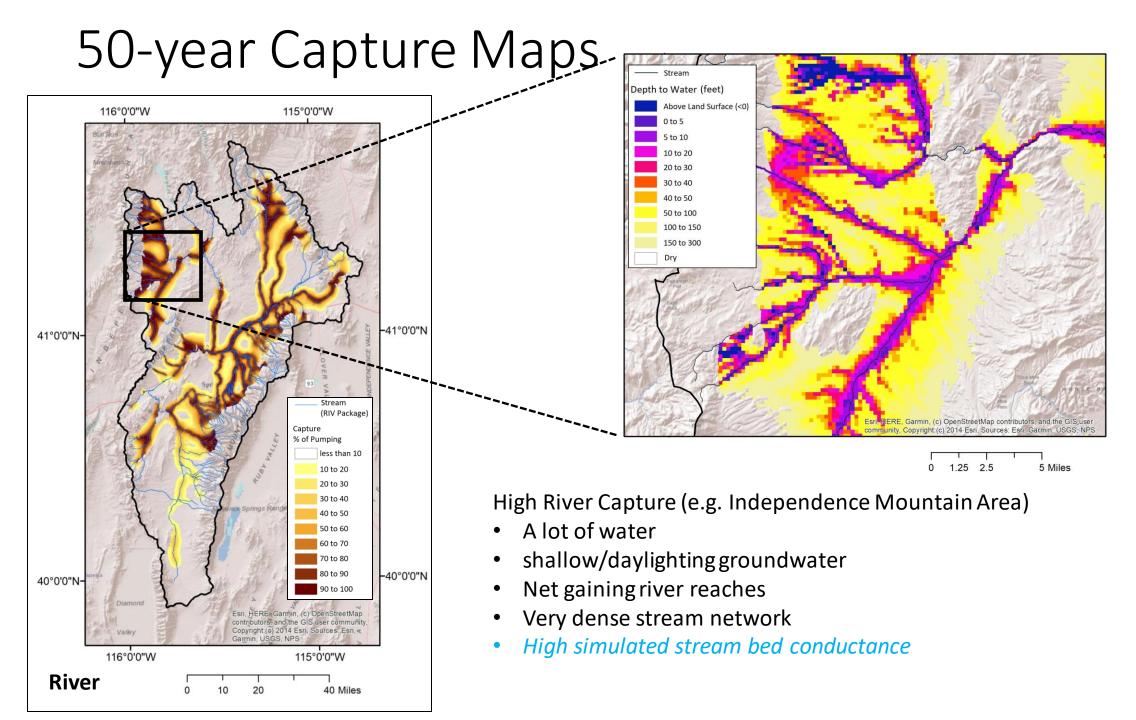

Year 50

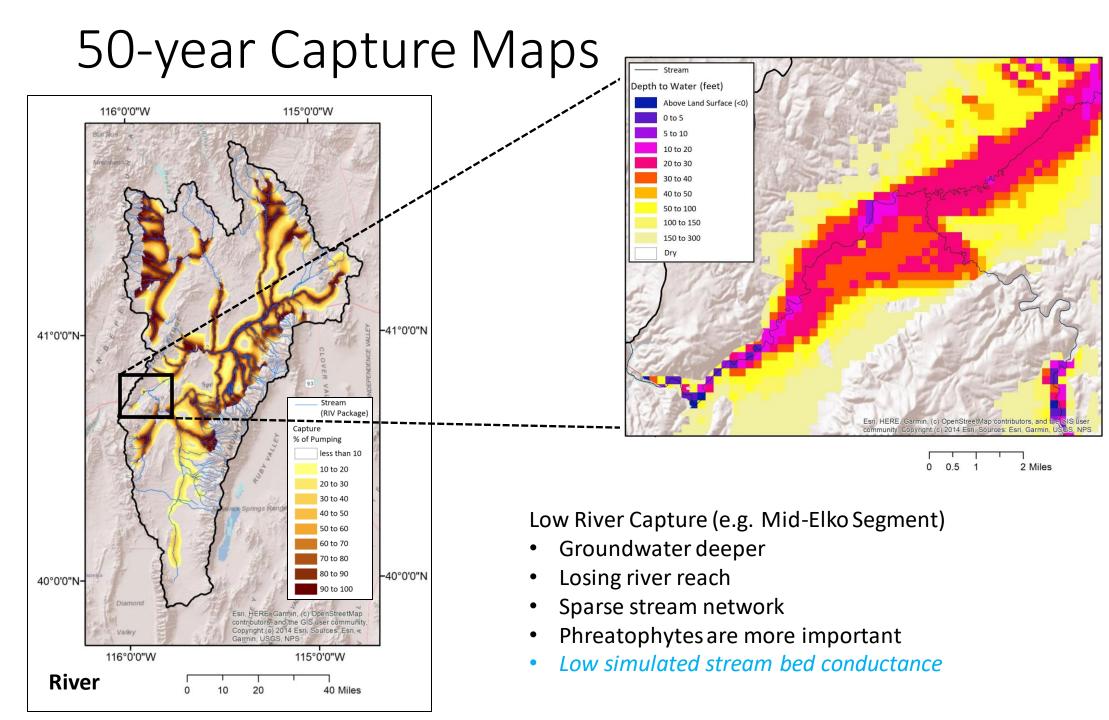

- Capture continues to increase and expand away from the river corridors
- Capture in dense stream networks merge.

* Model results are provisional and subject to change*

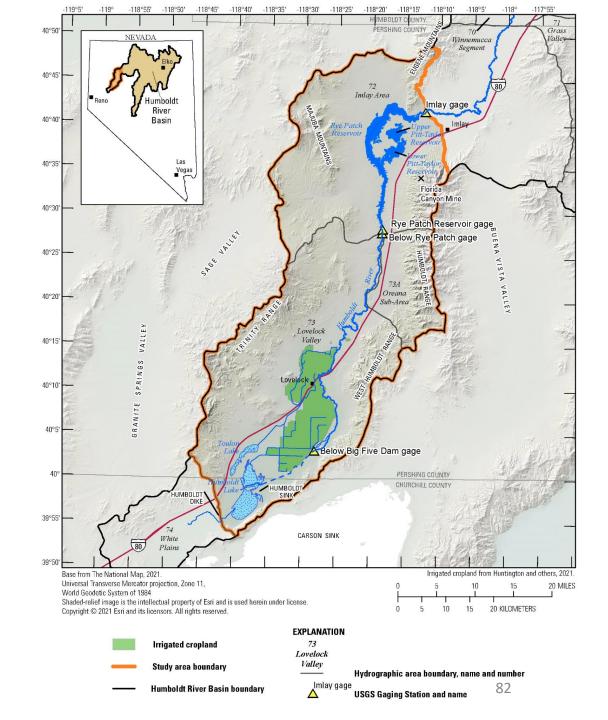

Model Domain

- 500 ft grid cell resolution
- Includes mountain block/bedrock
- 3 layers, generally representing clay (layer 1), alluvium/valley fill (layer 2), bedrock (layer 3)
- Thickness of clay layer set to 50 feet
- Depth to basement based on Ponce and Damar (2017) and used to define elevation of top of layer 3, with a minimum depth of 20 feet below land surface

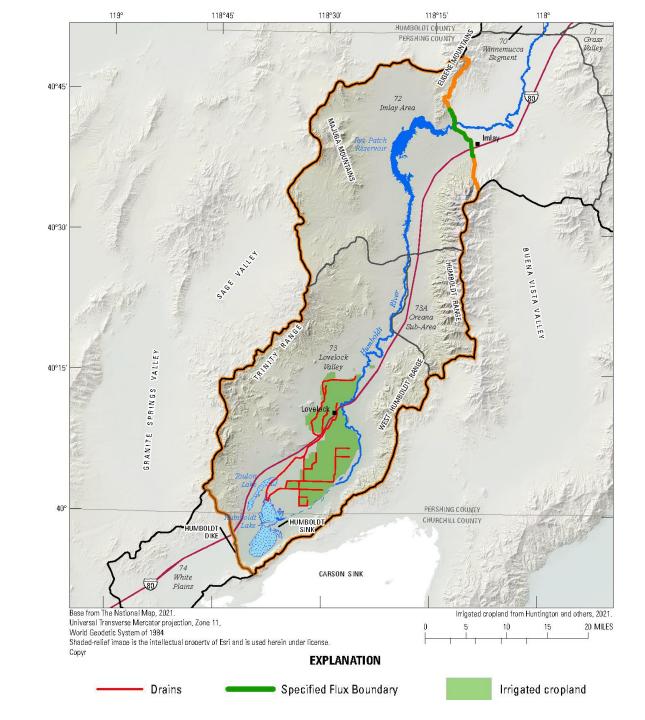

Lakes and River

- Humboldt River simulated using River package (RIV)
- Rye Patch Reservoir simulated as a constant head boundary (CHD) using mean annual stage
- Pitt-Taylor Reservoirs, Toulon Lake, and Humboldt Lake not simulated as they are frequently dry and heads are unknown
- River conductance calibrated to estimated steady-state river loss of 9,900 acre-feet/year
- Simulated loss of 100 AFA determined by model given calibration to ET in Imlay area and local heads

Interbasin Flow

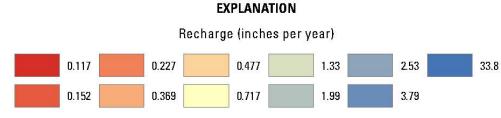

- Specified flux boundary applied along shared boundary with Middle Humboldt model (in review)
- Limited to extent of alluvial slope/fluvial deposits/playa/valley floor
- Inflow of 771 acre-feet per year based on current outflow from Middle Humboldt model

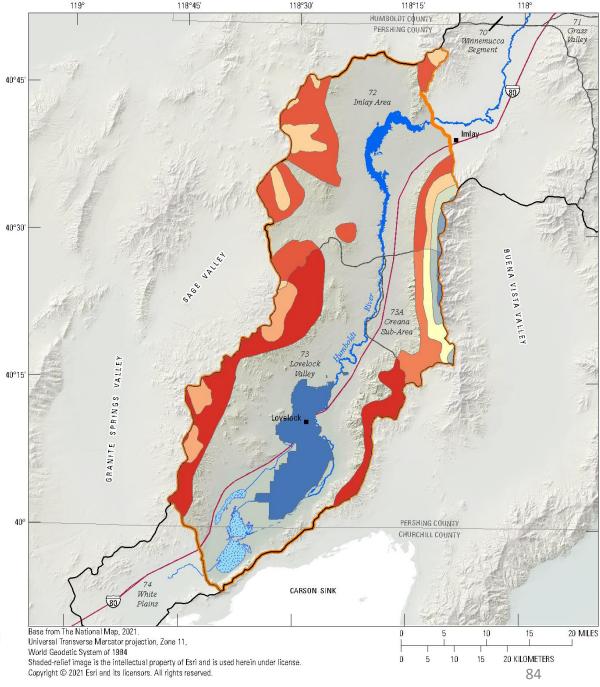

Recharge

	Moun	tain Blo			
Reference	Lovelock	Oreana	Imlay	Model Domain	Methodology
Everett and Rush, 1965	1,200	2,000			Maxey-Eakin, 1949
Eakin, 1962			4,000		Maxey-Eakin, 1949

- Mountain block recharge estimates from USGS Recon Reports distributed proportionally over Hardman map intervals
- Ag recharge rate applied as median of 1960-1990 regression (127,800 acre-feet per year)
- Simulated mountain block recharge = 5,700 acrefeet per year

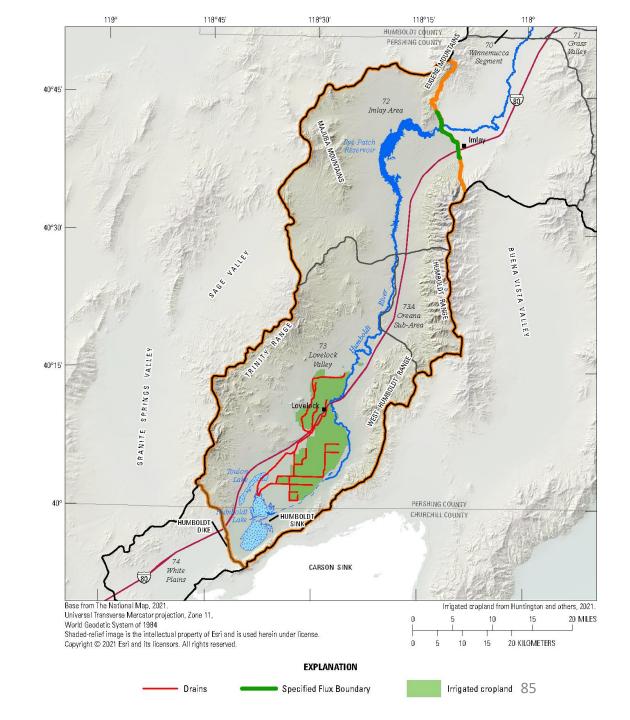

118°30

119°

118°45

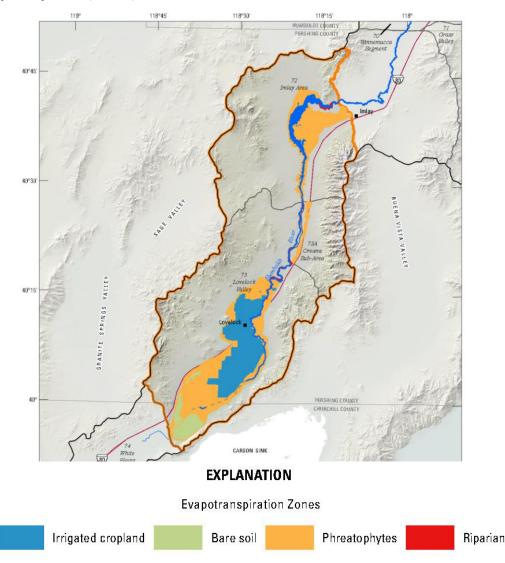

Drains

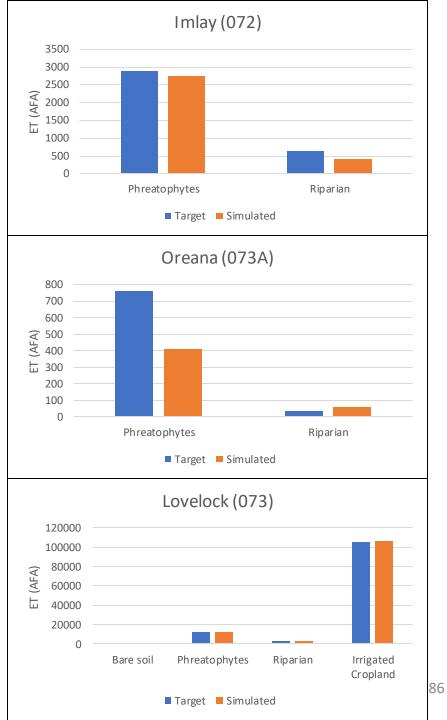

- Represents agricultural runoff/recharge lost to sink; simulated using the MODFLOW Drain (DRN) package
- Drain bottoms set to 9 ft bls
- Drain outflow estimated to be ~18,000 AFA

Evapotranspiration

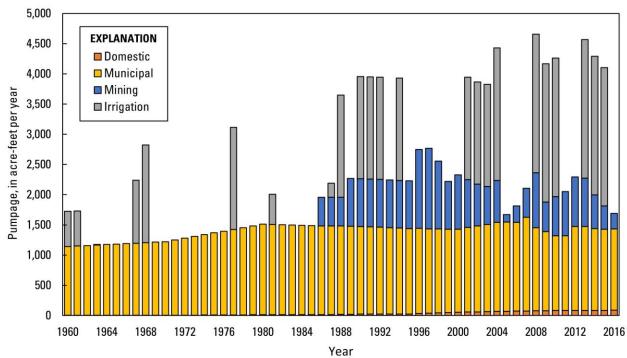

• ET zones applied over DRI polygons, estimated at 126,000 acrefeet per year (AFA).

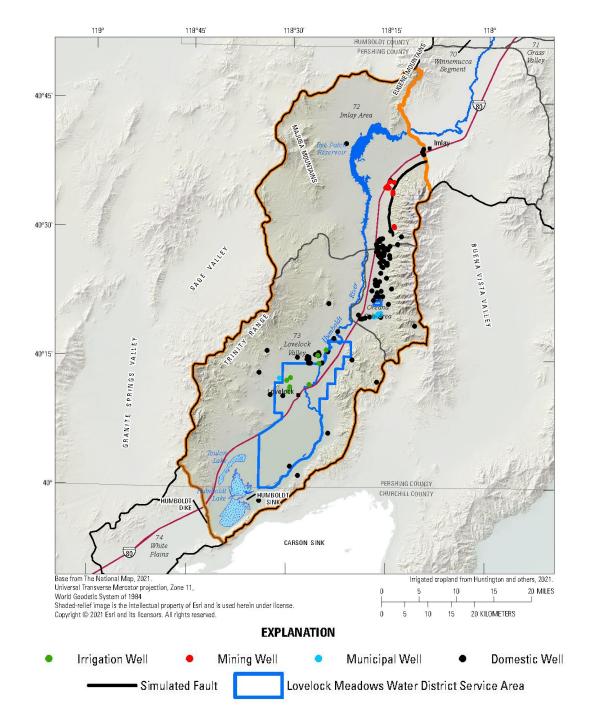

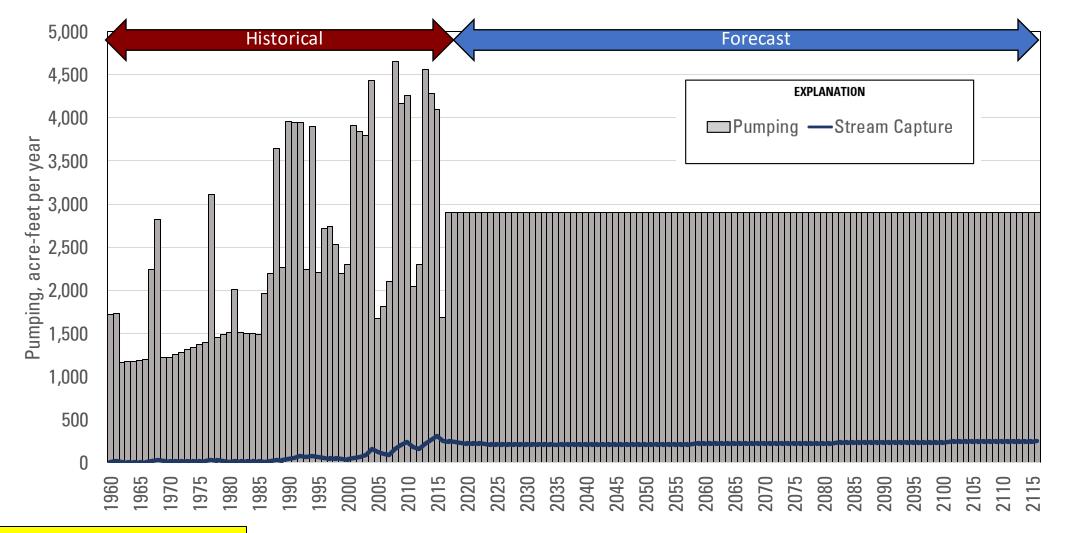

Transient Pumping

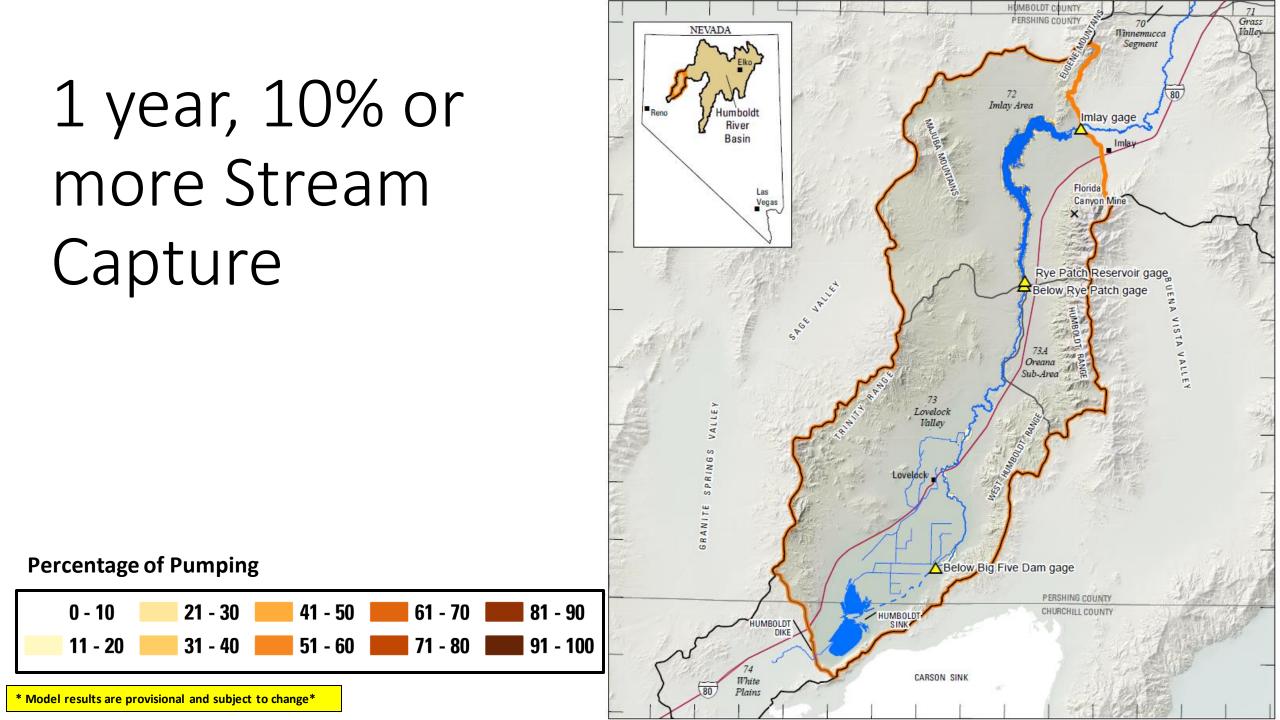

- Domestic wells pumping outside of Lovelock Meadows service area simulated at 0.7 acre-feet per year.
- Public supply wells pumped at rates extrapolated backwards to 1960 based on population.
- Mining well pumpage extrapolated earliest known rates backwards to 1986.
- Irrigation well pumpage inversely proportional to the ratio of estimated ag recharge relative to the mean agricultural recharge 1960-1990.

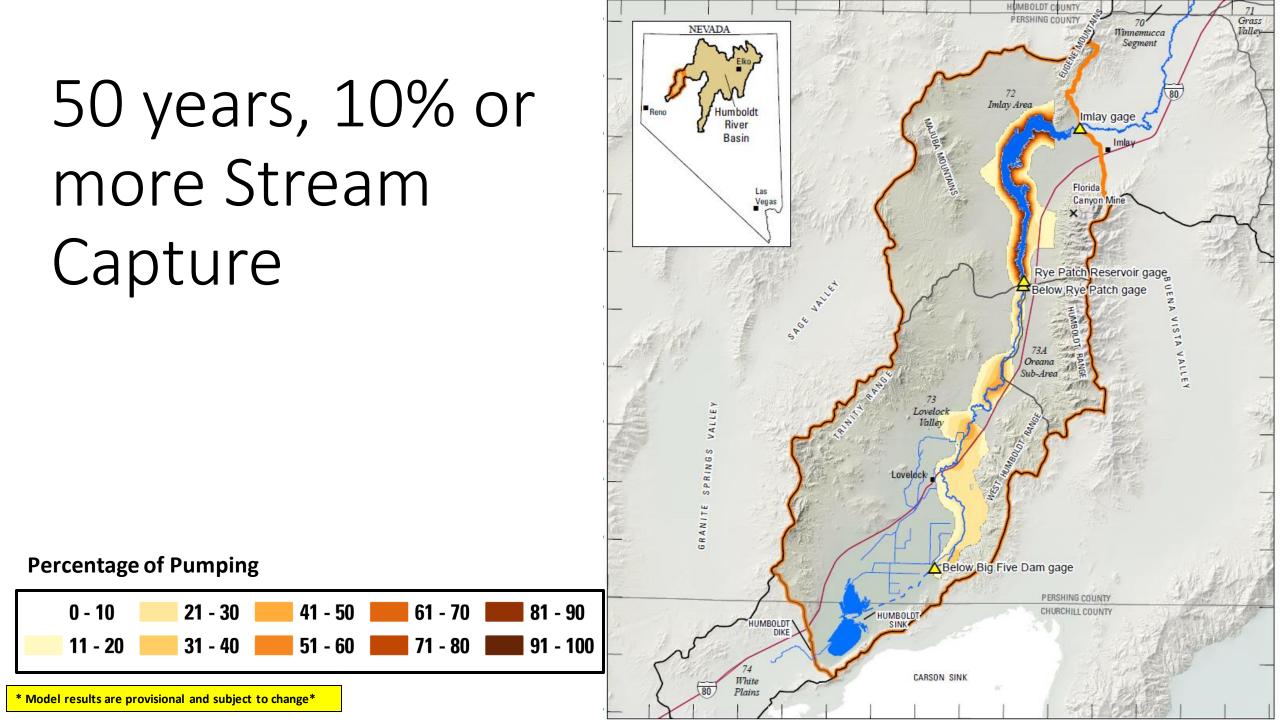

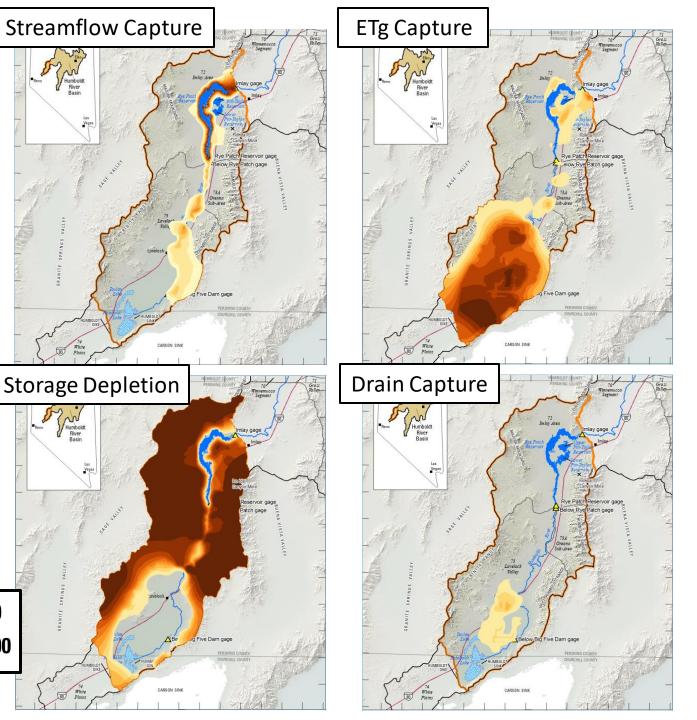

Estimated Humboldt River Historical and Predictive Stream Capture

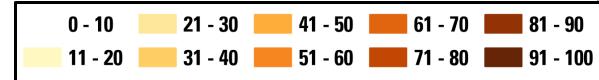

50 years, 10% or more all capture sources

Percentage of Pumping

COMPOSITE 50-YEAR CAPTURE MAP

NDWR

HUMBOLDT RIVER REGION 50-YEAR CAPTURE MAP

- Some disconnected reaches
- Mountains are masked
- Capture between models has different character
 - Upper has dense stream network.
 - Middle has many ephemeral/intermittent streams.
 - Lower represents finer/tighter aquifers
 - ET capturability differences.
- Boundary effects
 - External boundaries 'reflect' drawdowns

* Model results are provisional and subject to change*

END OF TECHNICAL PRESENTATIONS

ORDER 1329 OVERVIEW

NDWR

ORDER 1329 OVERVIEW

Acknowledges that groundwater pumping is causing stream capture that results in conflict.

New appropriations or water right changes that would increase capture from fully appropriated sources aren't being approved.

All applications reviewed and assessed for stream capture.

Capture is permissible if it can be offset by:

- Replacement surface water
- Withdrawn groundwater right with existing capture.

Establishes interim thresholds for capture offset.

Establishes goal of using Capture Studies for future capture management.

Articulates intent to establish public process to develop capture management framework.

IN THE OFFICE OF THE STATE ENGINEER OF THE STATE OF NEVADA

ORDER

#1329

ESTABLISHING INTERIM PROCEDURES FOR MANAGING GROUNDWATER APPROPRIATIONS TO PREVENT THE INCREASE OF CAPTURE AND CONFLICT WITH RIGHTS DECREED PURSUANT TO THE HUMBOLDT RIVER ADJUDICATION

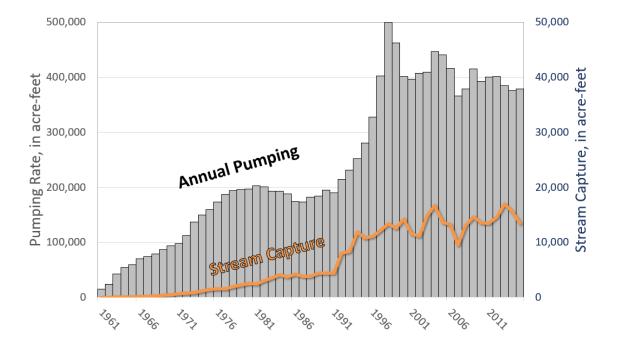

OVERVIEW

WHEREAS, it is well established that the source of water to a pumping well originates from three primary sources; first from groundwater storage, then increasing over time from capture of streamflow (where present in a hydrographic system) and evapotranspiration.^{1,2} The terms "stream capture" or simply "capture," as used in this Order, refer to a reduction in streamflow caused by groundwater pumping. Decades of groundwater pumping in the Humboldt River Region (Region) has led to increasing capture of the Humboldt River and its tributaries, resulting in growing conflict with rights of the Humboldt Decree.

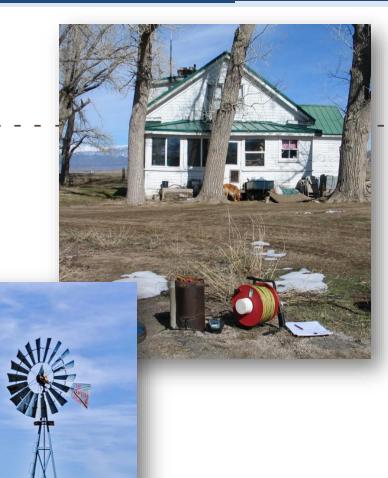

ORDER 1329 DOES NOT:

Predetermine the final capture management framework.

Apply to domestic well use or minor stock water use (<5 afy of capture in 50 yrs).

Provisional estimated Historical Capture for middle Humboldt River Basin*

TECHNICAL ASPECTS

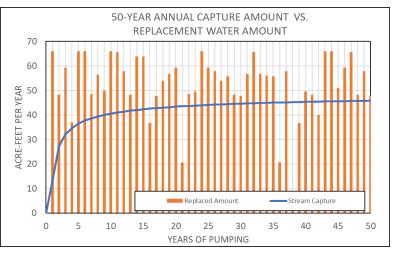

Objective:

Utilize existing SW or GW right to avoid increasing capture that would otherwise cause conflict

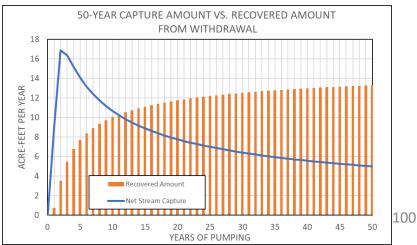

Interim Thresholds:

- Evaluation Threshold
 - >10% capture after 50 years
- Long-term Threshold (50-yr Rule)
- Annual Threshold (80% Rule)

Replacement by SW Right

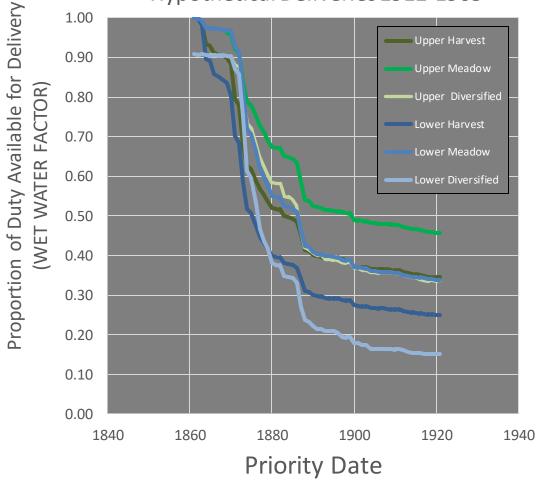

GW Right Withdrawal

DETERMINATION OF SURFACE WATER AVAILABILITY FOR REPLACEMENT ("WET WATER")

Wet Water Factors based on Mean Annual Hypothetical Deliveries 1912-1965

Provisional*

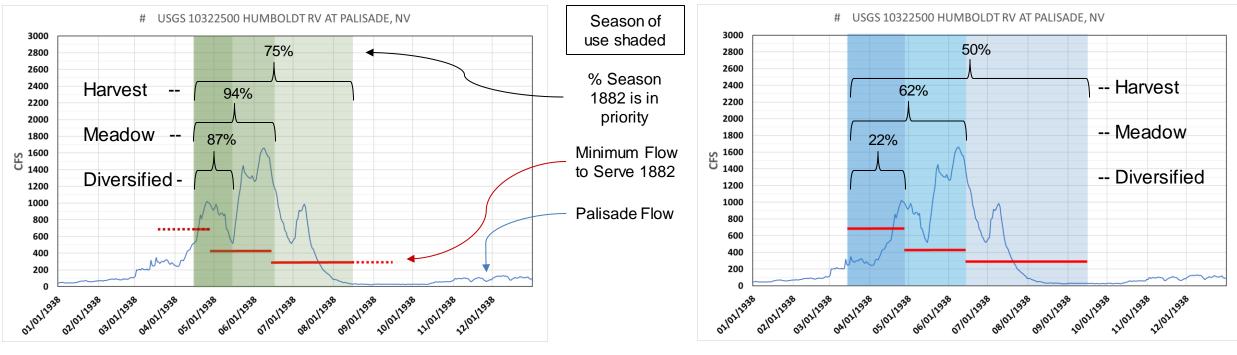

WHAT AFFECTS WET WATER DETERMINATION?

1882 PRIORITY EXAMPLE:

- Typical Year, 208,000 afs
- Delivery based on Palisade Flow

Upper Rights "wetter" than Lower Rights

- Shorter Season of Use
- Sweet spot of runoff

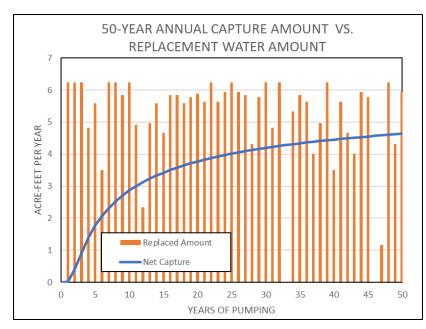

Upper Humboldt Delivery

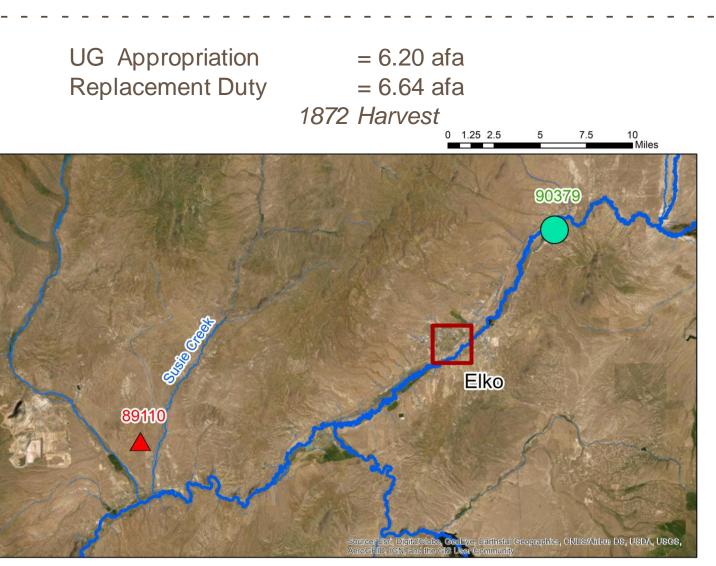

Lower Humboldt Delivery

REPLACEMENT WATER EXAMPLE

89110 (UG) 90379 (Replacement)

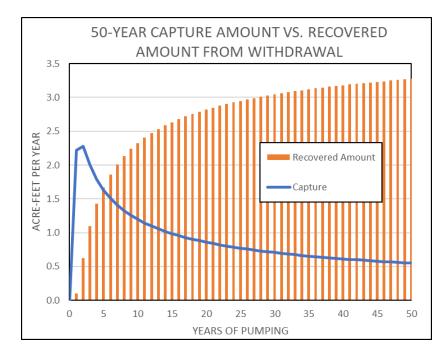

*Supports ~5% Stream Loss

WITHDRAWAL OF GROUNDWATER EXAMPLE

41509 (Existing Right)90466 (Proposed Change)

Existing= 7.75 afaChanged Duty= 3.16 afaWithdrawn= 4.59 afa

0 0.25 0.5 1 Miles

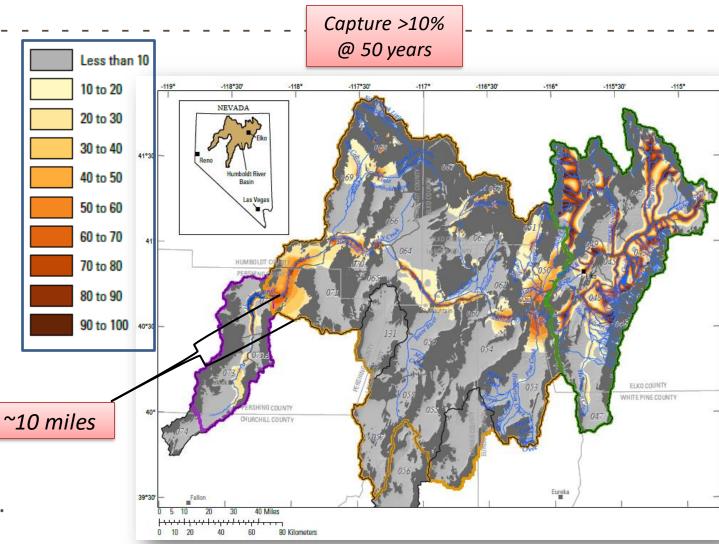

EXEMPTIONS

- Applications whose proposed PODs cause capture at <10% during 50-year period
- Change applications whose proposed PODs cause same or less capture than existing PODs
- Applications whose proposed PODs cause < 5 afy capture during 50-year period
- Temporary change applications to provide for multiple PODs from Mining, Milling, and Dewatering operations (Centralized POD)

TAKE HOME MESSAGES

- UG Applications within ~10 miles of fully appropriated stream likely be in capture zone.
- Applications for <5 afy are generally exempt.
- Applications that would otherwise be denied, can be approved if capture can be offset.
- Thresholds and criteria are interim and subject to capture management framework.

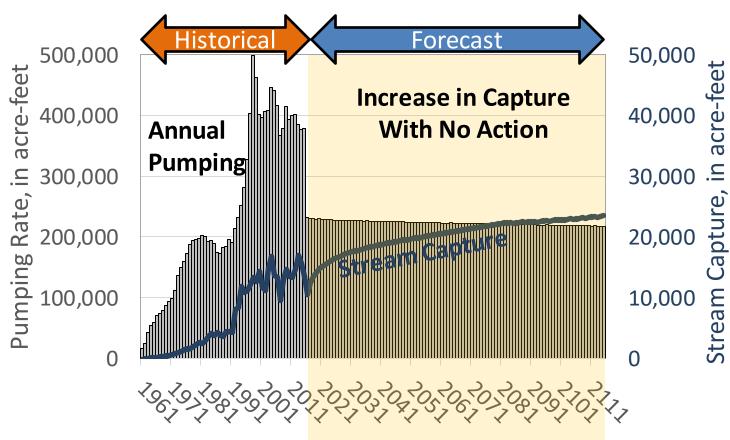

MOVING FORWARD WITH CONJUNCTIVE MANAGEMENT FRAMEWORK

NDWR

WHERE ARE WE GOING FROM HERE?

Develop capture management framework with Stakeholders for managing existing capture.

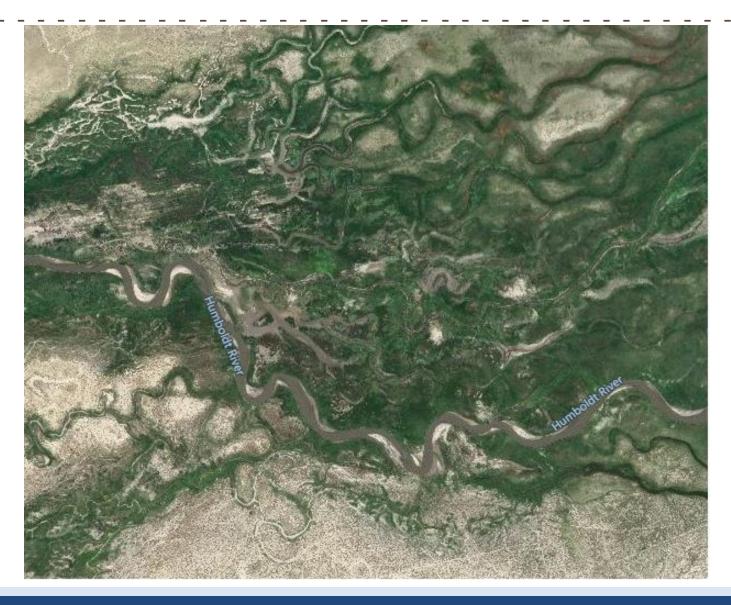

Examples of potential future strategies

- Curtailment in capture threshold areas
- Offset credit for artificial recharge
- Enhanced storage through ASR
- Conservation funds to purchase water rights with greatest conflict
- Private party agreements to resolve conflict
- Withdrawal/abandonment of committed rights

Provisional estimated Historical and Forecasted Capture for middle Humboldt River Basin*

MOVING FORWARD WITH CONJUNCTIVE MANAGEMENT
